Disclaimer

These slides are intended as presentation aids for the lecture. They contain information that would otherwise be to difficult or time-consuming to reproduce on the board. But they are incomplete, not self-explanatory, and are not always used in the order they appear in this presentation. As a result, these slides should not be used as a script for this course. I recommend you take notes during class, maybe on the slides themselves. It has been shown that taking notes improves learning success.

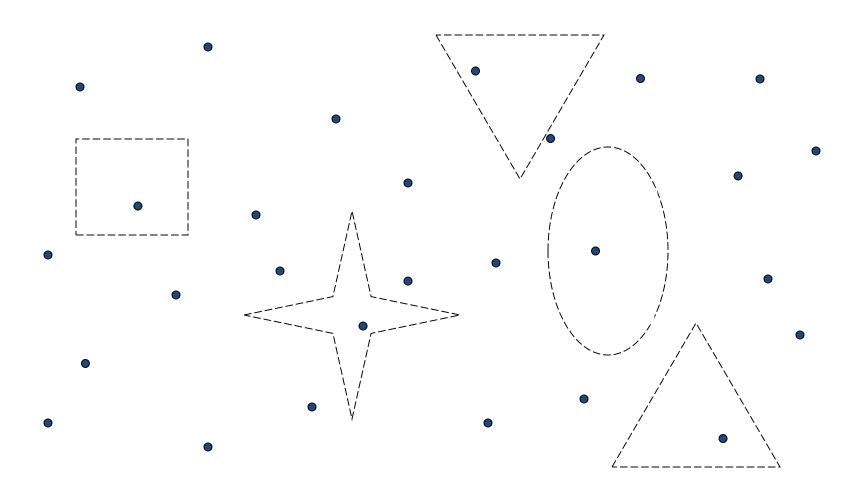

Robotics

Sampling-based Multi Query Motion Planning

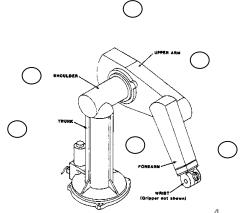

TU Berlin Oliver Brock

Sampling Configuration Space

Basic Primitive: Collision Detection

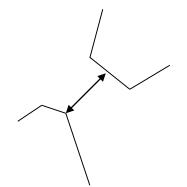

- Computational complexity collision detection
 - n objects have $O(n^2)$ interactions
 - Robot with l links and n obstacles has O(l * n)
 - Each object has many features 1000s!!!
 - In practice a costly operation

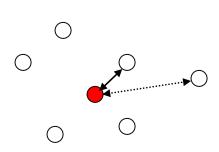

Tricks for Distance Computation

- Exploit spatial coherency
 - Group primitives hierarchically
 - Exploit adjacency (on single object)
- Exploit temporal coherency
 - Exploit former relation between multiple objects
- Heuristics are good
- Problem remains computationally complex

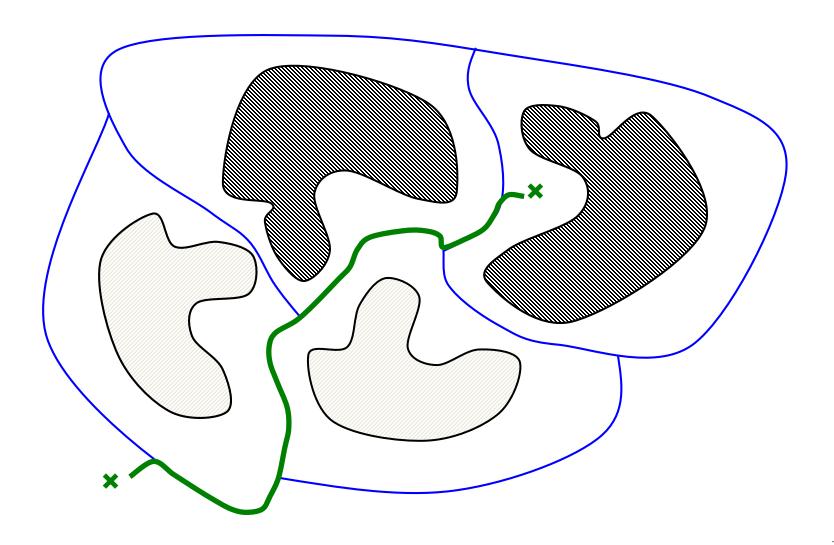

What is the perfect roadmap?

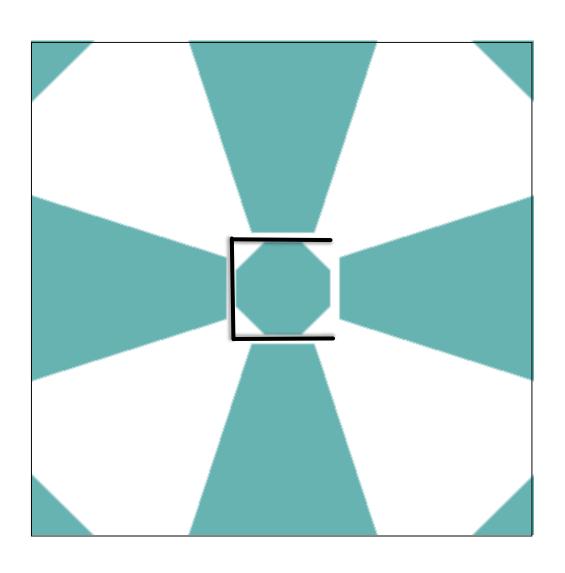

An Ideal Roadmap

- Any point in C-space should be connectable to the roadmap
- If there is a path between two points in Cspace the roadmap should contain a path between them after they were connected to the roadmap

 How can such a roadmap be obtained through sampling?

Perfect Roadmap

Exploration versus Exploitation

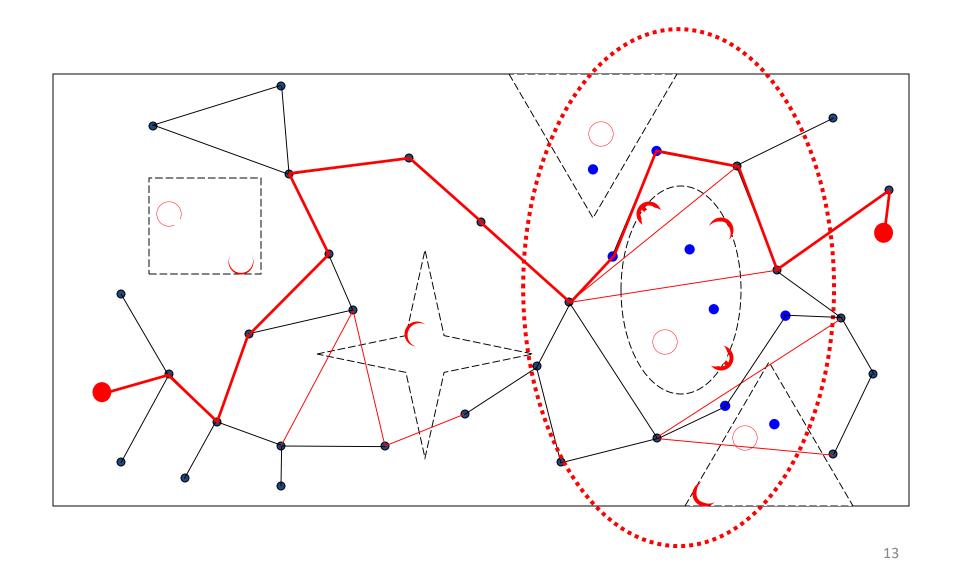

Exploration seeks **understanding of the state space**, irrespective of a particular task. In motion planning, the process **exploration** seeks to understand the connectivity of the configuration space, irrespective of solving a particular motion planning problem.

Guided exploration seeks **efficient understanding of the state space**, irrespective a particular task, by **leveraging available information**.

Exploitation strives to **accomplish a particular task** as **efficiently as possible** by **leveraging available information**.

In motion planning, **exploitation** seeks a valid path for a **particular task**, based on available information.

Probabilistic Roadmap (PRM) Planner

Probabilistic Roadmap Planner

Construction

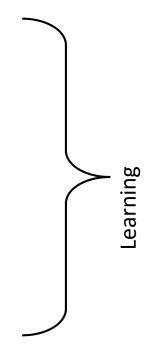

- Generate random configurations
- Eliminate if they are in collision
- Use local planner to connect configurations

Expansion

- Identify connected components
- Resample gaps
- Try to connect components

Query

- Connect initial and final configuration to roadmap
- Perform graph search

Learning Phase

Construction

- R = (V,E)
- repeat n times:
 - generate random configuration
 - add to V if collision free
 - attempt to connect to $\underline{\textit{neighbors}}$ using $\underline{\textit{local planner}}$, unless in same connected component of R

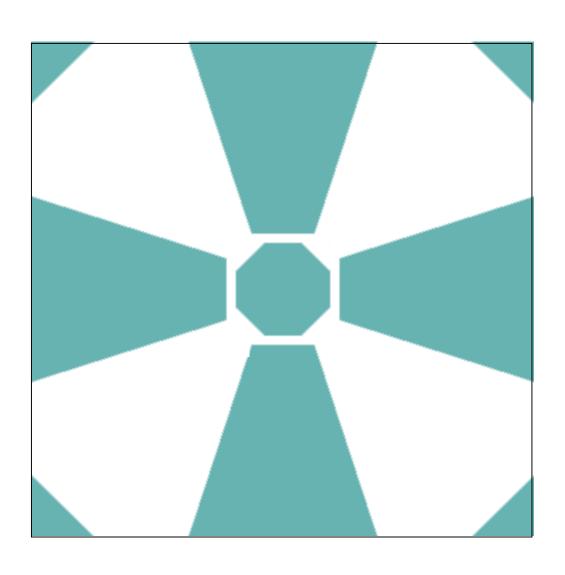

Expansion

- repeat k times:
 - select <u>difficult</u> node
 - attempt to connect to neighbors using <u>another local planner</u>

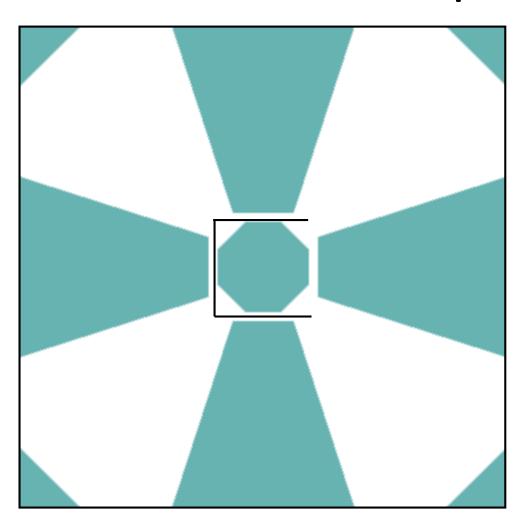

Query

- Connect start and goal configuration to roadmap using local planner
- Perform graph search on roadmap
- Computational cost of querying neclegible compared to construction of roadmap

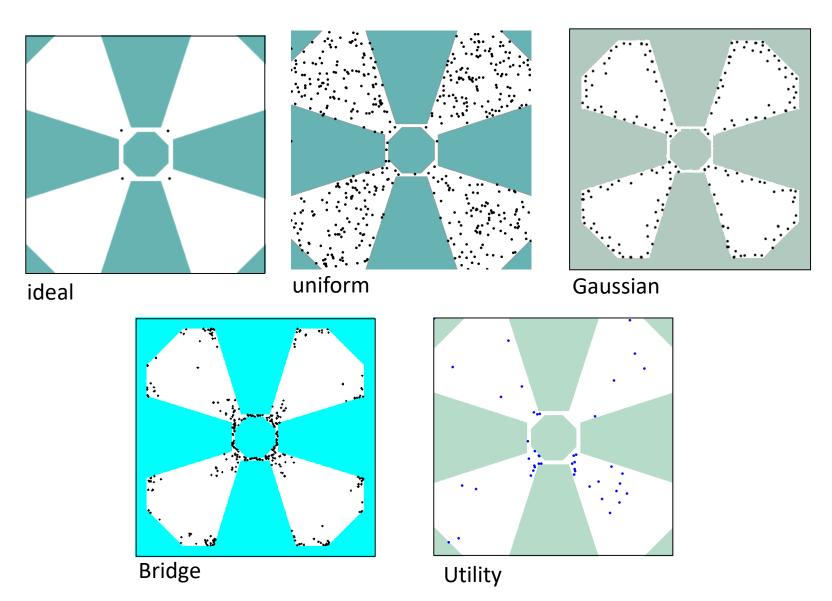

Perfect Sampling

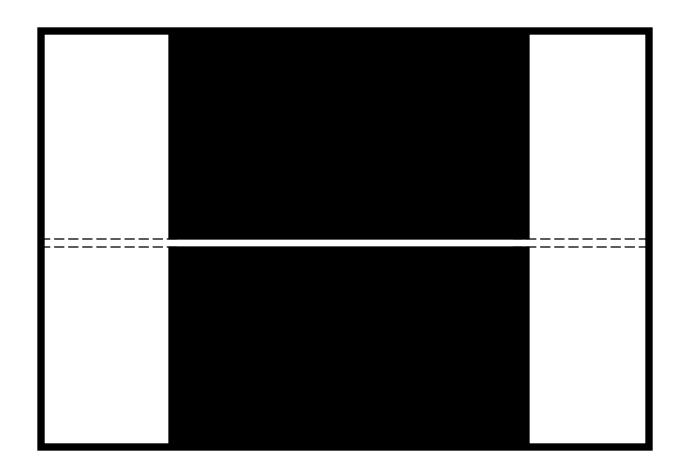

Perfect Roadmap

Different Sampling Strategies

Narrow Passage Problem

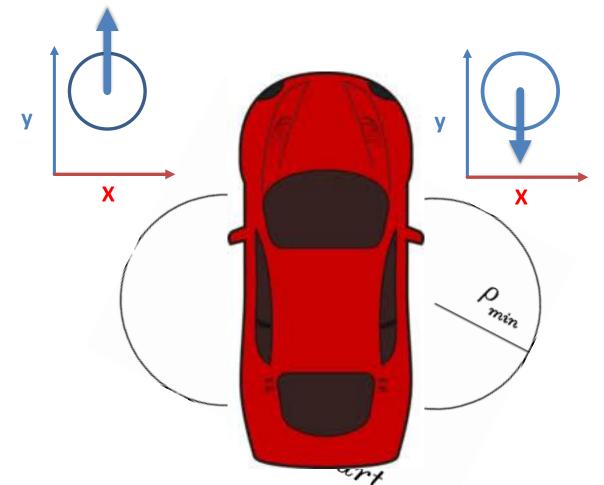

Key to Good Sampling: Exploiting Structure

- Identify underlying structure
- Represent information about structure
- Exploit information
- Structure can come from
 - sampling
 - problem description

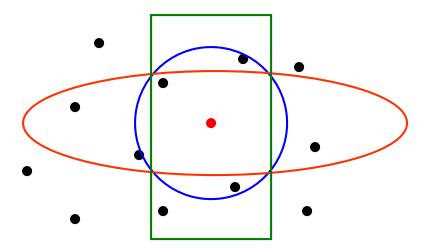

Neighbors

• Use distance metric to determine neighbor

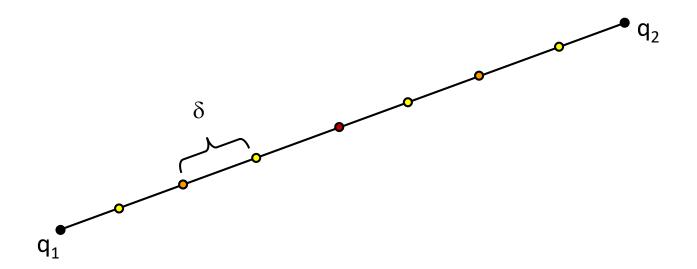

Neighbors

- Use distance metric to determine neighbor
- Euclidian distance oftentimes used
- Others possible:
 - maximum Euclidian distance
 - maximum joint difference

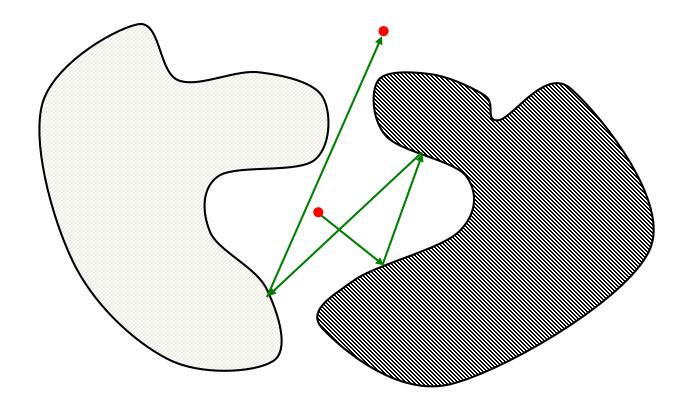

Local Planner

tests up to a specified resolution $\delta!$

Another Local Planner

perform random walk of predetermined length; choose new direction randomly after hitting obstacle; attempt to connect to roadmap after random walk

PRM Limits Local Planners

- Consider car-like robot
- Connecting configurations might be difficult
- Goal: provide probabilistic method for kinematic and dynamic constraints
 - Car-like
 - Satellite
 - Plane
- Idea: Let local planner choose configurations

Summary: PRM

- Algorithmically very simple
- Surprisingly efficient even in high-dimensional C-spaces
- Capable of addressing a wide variety of motion planning problems
- One of the hottest areas of research
- Allows probabilistic performance guarantees
- BUT: narrow passage problem!

Exploration versus Exploitation

Exploration seeks **understanding of the state space**, irrespective of a particular task. In motion planning, the process **exploration** seeks to understand the connectivity of the configuration space, irrespective of solving a particular motion planning problem.

Guided exploration seeks efficient understanding of the state space, irrespective a particular task, by leveraging available information.

Exploitation strives to accomplish a particular task as efficiently as possible by leveraging available information. In motion planning, exploitation seeks a valid path for a particular task, based on available information.

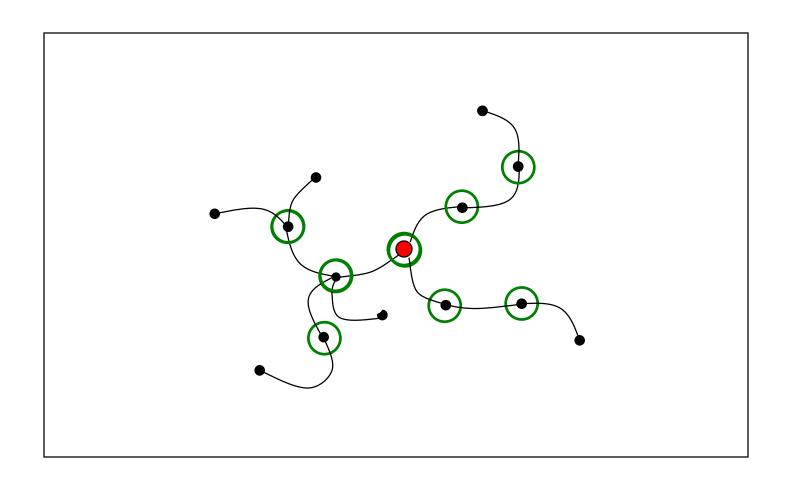

Robotics

Sampling-based Single Query Motion Planning

TU Berlin Oliver Brock

Rapidly-Exploring Random Trees (RRT)

Rapidly-Exploring Random Trees (RRT)

```
T.add_vertex(q<sub>init</sub>)
Repeat k times:
   q_{rand} = SAMPLE()
   q_{near} = NEAREST_VERTEX(q_{random})
   q_{new} = LOCAL_PLANNER(q_{near}, q_{random}, \Delta q)
   T.add_vertex(q<sub>new</sub>)
   T.add edge(q_{near}, q_{new})
return(T)
```

Rapidly-Exploring Random Trees (RRT)

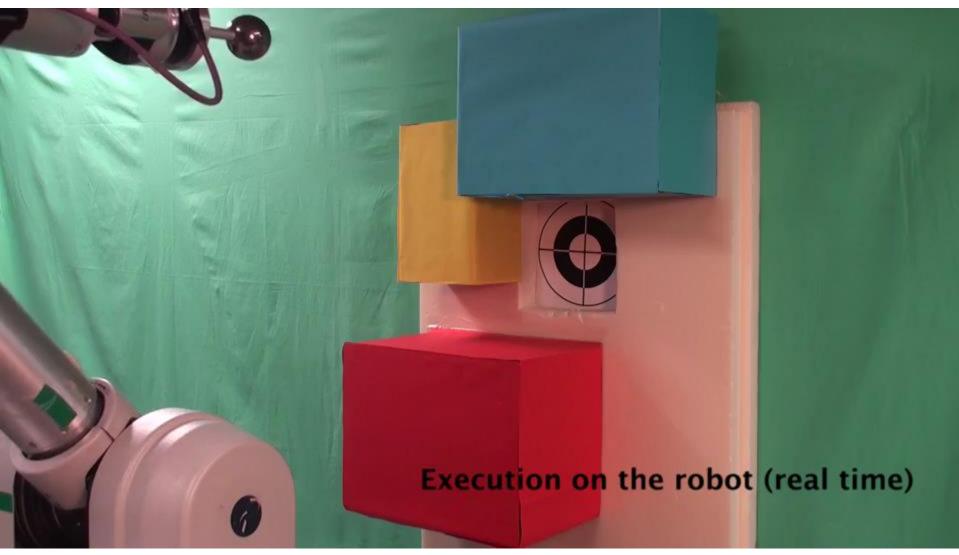

```
T.add_vertex(q<sub>init</sub>)
Repeat:
    q_{rand} = SAMPLE()
    q_{near} = NEAREST_VERTEX(q_{random})
    q_{new} = LOCAL_PLANNER(q_{near}, q_{random}, \Delta q)
    if VALID(q<sub>near</sub>, q<sub>new</sub>)
            T.add vertex(q_{new})
             T.add_edge(q<sub>near</sub>, q<sub>new</sub>)
             LOCAL_PLANNER(q<sub>new</sub>, q<sub>goal</sub>,-)
             if VALID(q<sub>new</sub>, q<sub>goal</sub>)
                     return(T)
```

Kinodynamic Planning with RRT

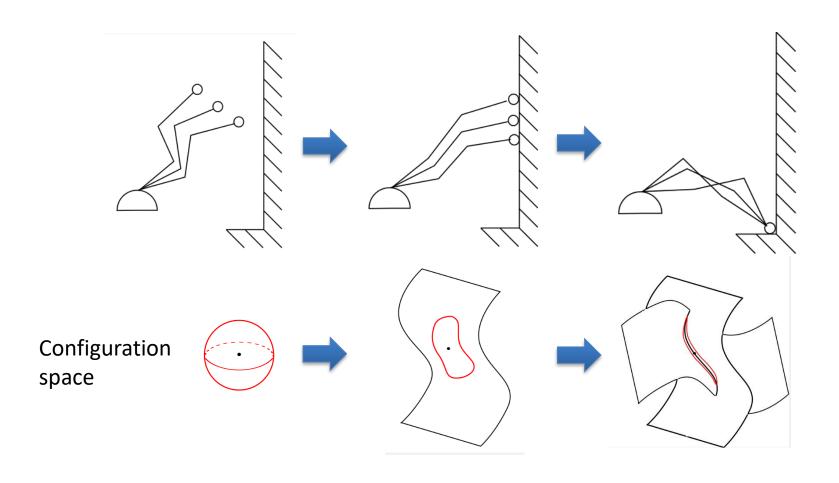

- Easy to integrate local planners for
 - Kinematic constraints
 - Dynamic constraints
- Expand C-space to state space for velocity representation (2 d dimensions)
- Requires known dynamic model (grasping!)
- Planning times for 7 dof ~ 10-20 seconds (holonomic, no dynamics)

What did we ignore until now?
